

Trilobites – Adriana and Tessa

The trilobite was an arthropod that lived during the warm seas times. It ate plants in the seas. It had a lot of legs. It had bones on the outside. It was egg shaped. Their eyes could turn around in a full circle.

It protected itself from other animals by scurrying away and using his hard back. Some trilobites could roll up into a ball. We know that this animal lived long ago because scientists found its outside skeleton and we found fossil evidence at Penn Dixie.
